

Linkage

-Genes on the same chromosome are called linked

Human

-23 pairs of chromosomes, ~35,000 different genes expressed.

- average of 1,500 genes/chromosome

Chromosome 18

Chromosome 19

Chromosome 20

Chromosome 17

Key

AMY	Amylase (Salivary and Pancreatic)
AT3	Antithrombin (Clotting Factor IV)
CB	Colorblindness
DMD	Duchenne Muscular Dystrophy
FHM	Fumarate Hydratase (Mitochondrial)
GDH	Glucose Dehydrogenase
G6PD	Glucose-6-Phosphate Dehydrogenase
HEMA	Hemophilia A (Classic)
HGPRT	Hypoxanthine-Guanine-Phosphoribosyl Transferase (Lesch-Nyhan Syndrome)
PEPC	Peptidase C
PGK	Phosphoglycerate Kinase
PGM	Phosphoglucomutase
Rh	Rhesus Blood Group (Erythroblastosis Fetalis)

Following Meiosis

Parental chromosomal types

- complete linkage and no crossing over.
Seldom occurs.**

Nonparental chromosomal types

- result from crossing-over, recombination
of alleles.**

Crossing-Over

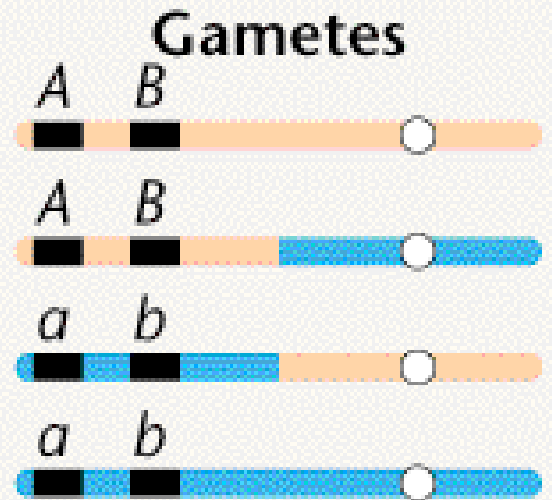

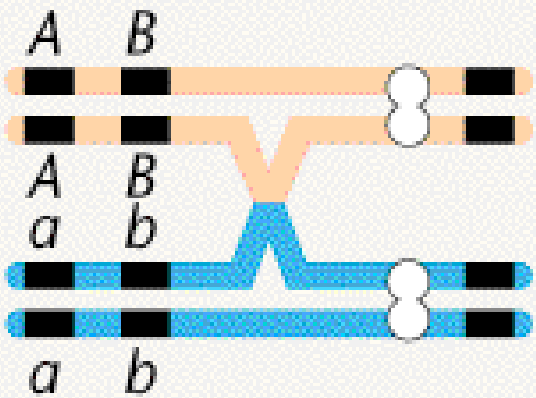

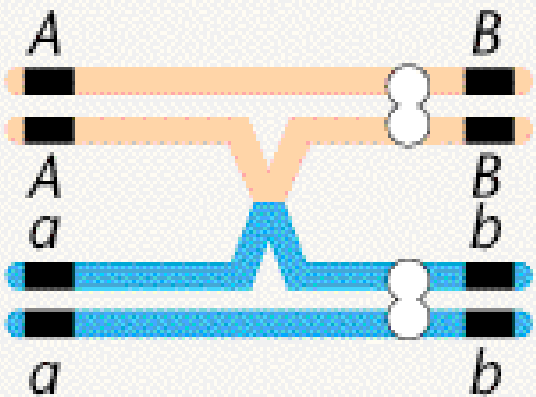

Figure 9.16

(a) Exchange

Exchange occurs but does not intervene between the genes

(b) Exchange

Exchange occurs and does intervene between the genes

- Frequency of crossing-over between linked genes is proportional to the distance between them.**
- Possible if two genes are close that crossing-over will not be detected.**
- crossing-over has been used to construct chromosome maps.**

Three possibilities for two genes:

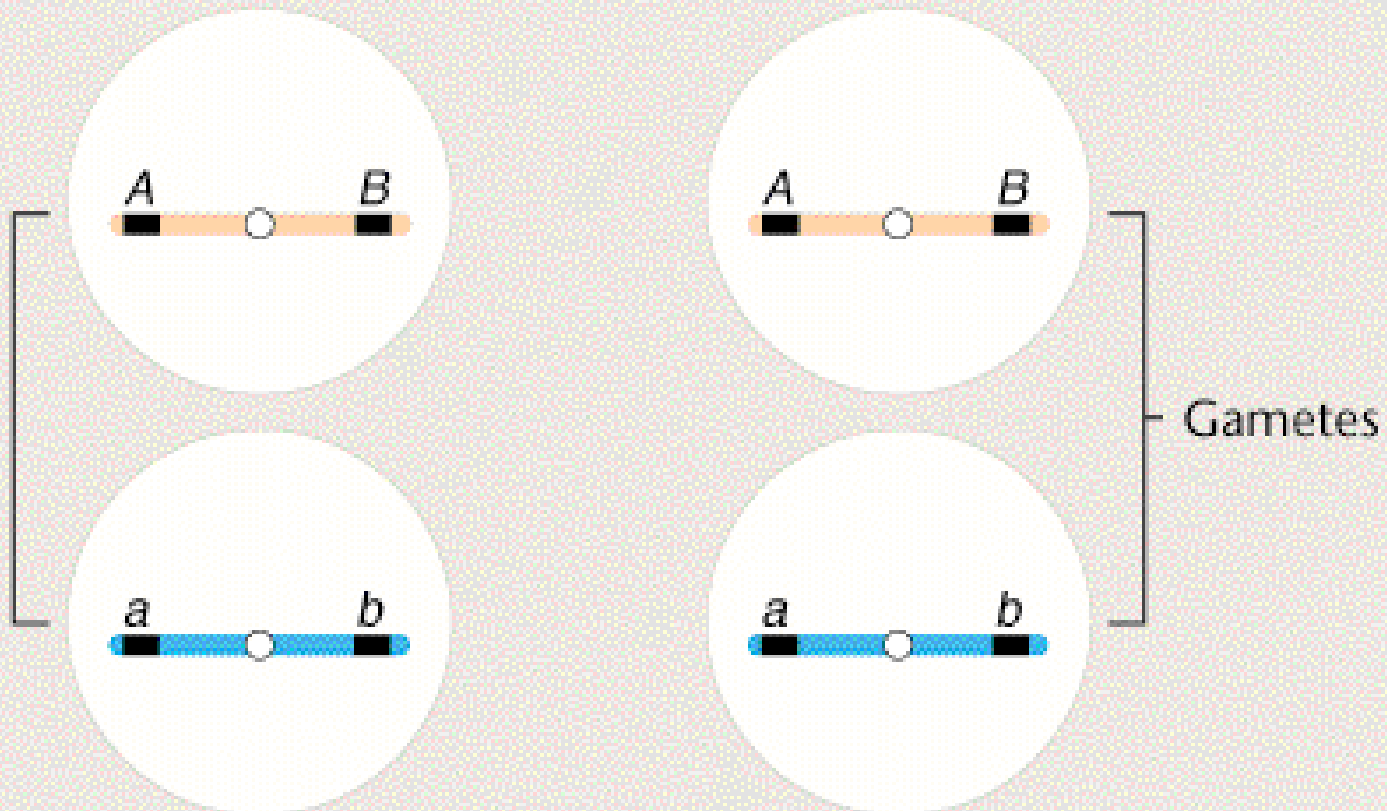

Fig. 6.1 in text.

- a. On separate chromosomes so segregate independently.**
- b. Both genes on same pair of chromosomes, no crossing-over so always stay together.**
- c. Both genes on same pair, crossing over, produces recombinant gametes.**

(a) Independent assortment of two genes on two different homologous pairs of chromosomes

(b) Linkage between two genes on a single pair of homologs: no exchange occurs

(c) Linkage between two genes on a single pair of homologs: exchange occurs between two nonsister chromatids

Possible for two genes to be far enough apart so number of recombinants approaches 50%.

Four types of gametes produced in a 1:1:1:1 ratio.

Linkage ratio

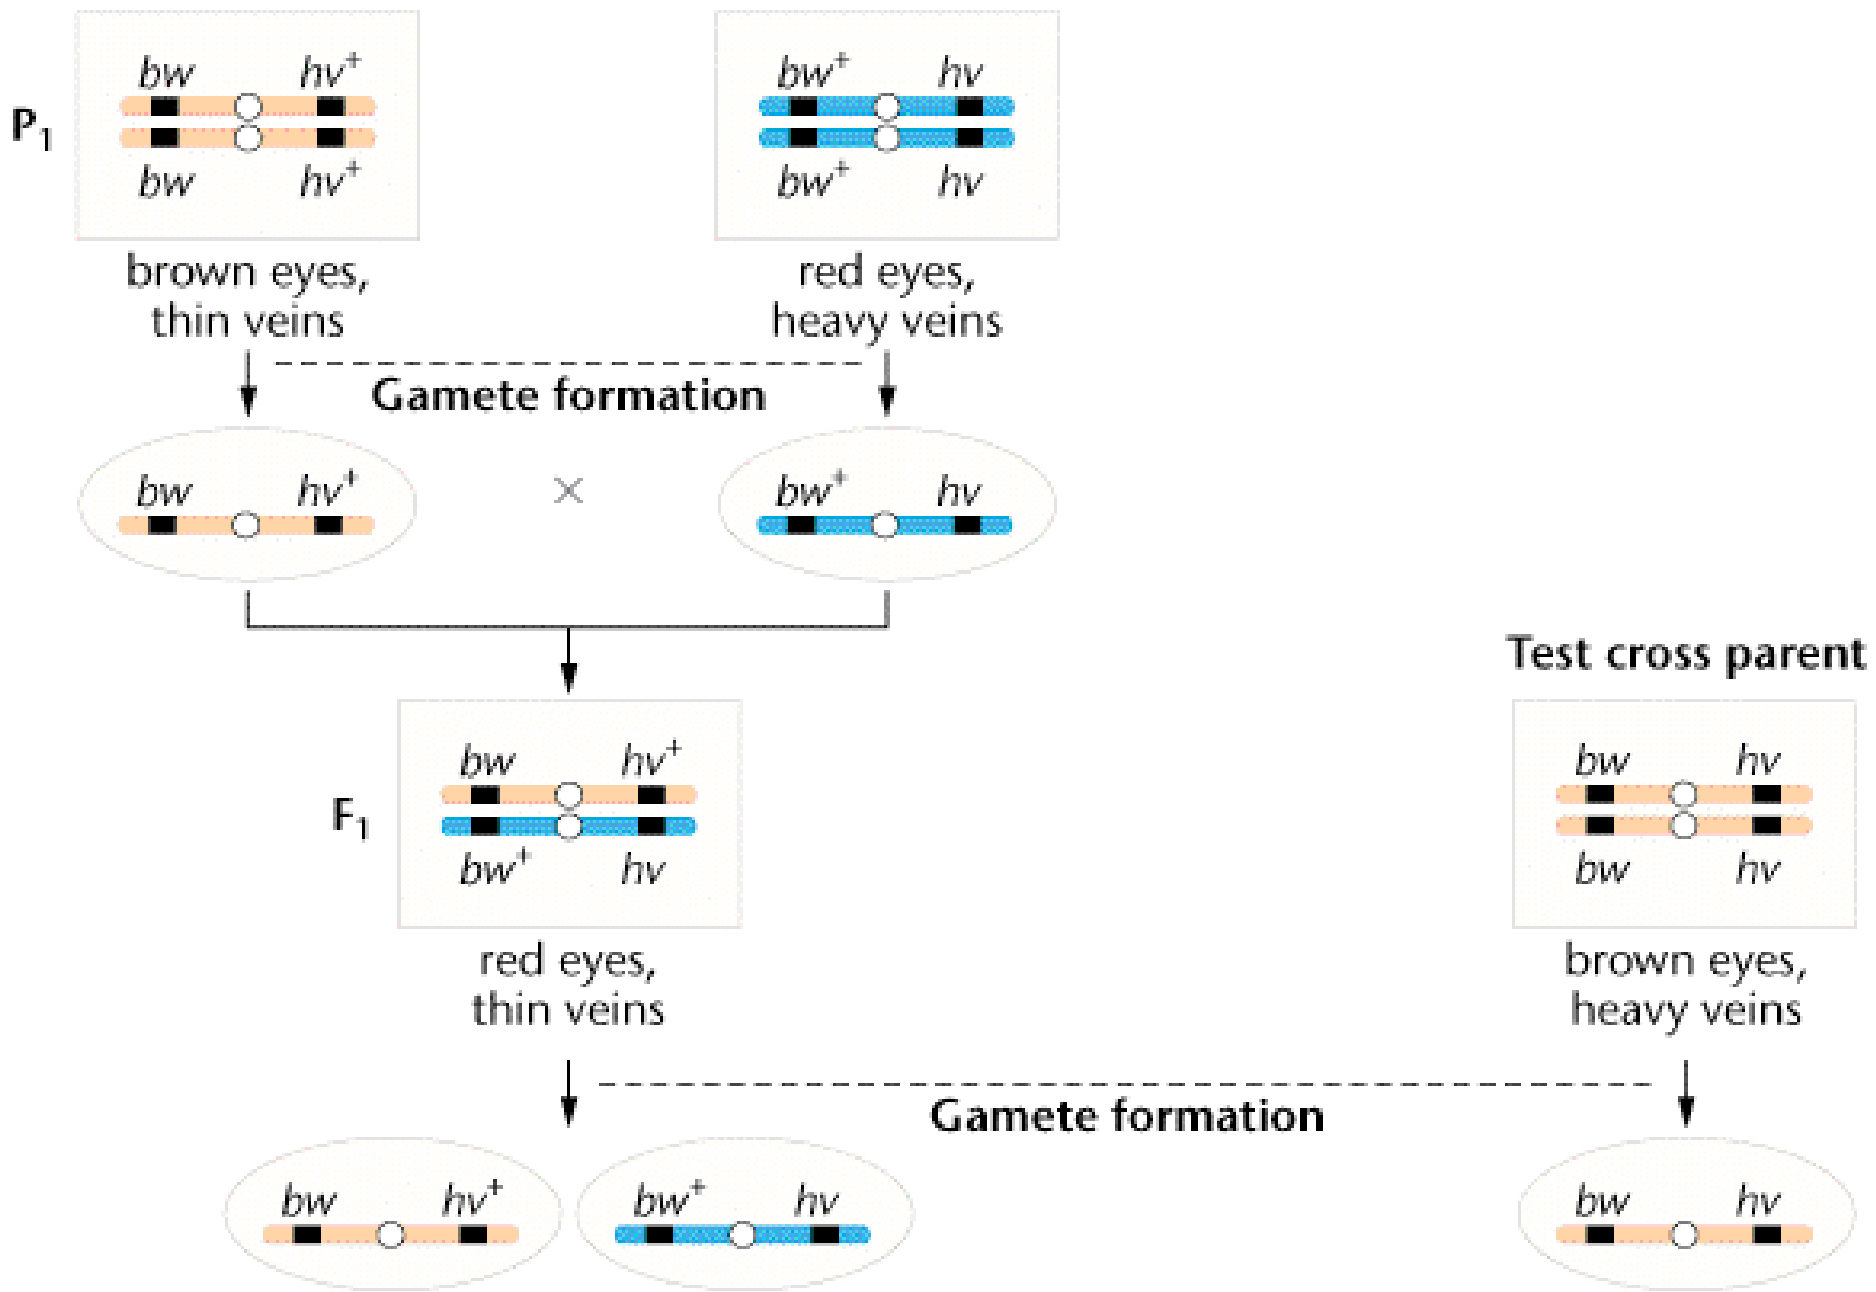

If complete linkage, a unique F_2 phenotypic ratio results.

1:2:1 phenotypic and genotypic ratio

Test cross produces 1:1 ratio

Genetic Symbols

P₁ : bw hv⁺ bw⁺ hv
———— X ————
bw hv⁺ bw⁺ hv

(a) F₁ × F₁

F₂ generation

1/4 brown, thin: 2/4 red, thin: 1/4 red, heavy
1 : 2 : 1 ratio

(b) F₁ × Test cross parent

Test cross progeny

1/2 brown, thin: 1/2 red, heavy
1 : 1 ratio

Genes located on same chromosome will show evidence of linkage.

Linkage groups

- number equals haploid number of chromosomes.

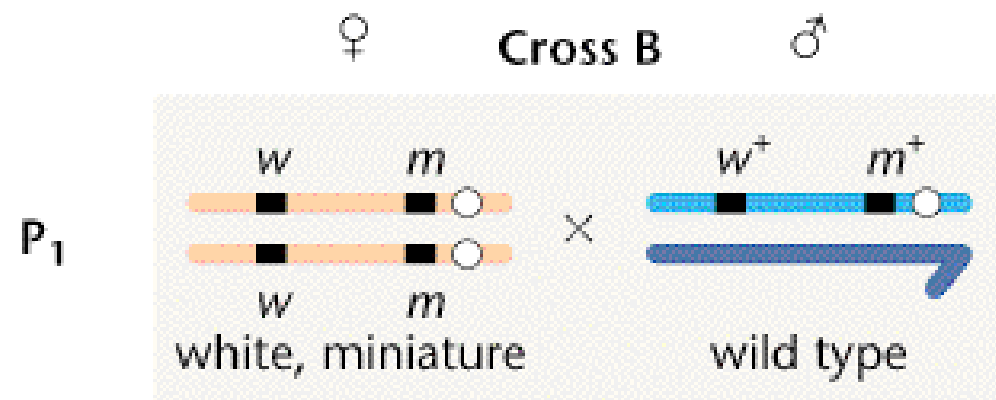

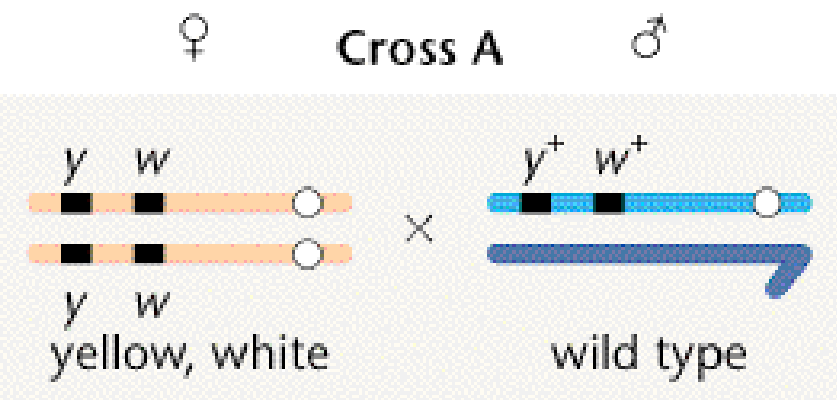

Complete linkage is rare, usually some crossing-over.

Thomas Hunt Morgan

- first discovered sex-linkage.**
- linked genes can become separated**
- How did genes that were linked become separated?**
- Why did the frequency of separation vary depending on the gene?**

Thomas Hunt Morgan

Morgan proposed:

During Meiosis, synapsed chromosomes exchanged genetic material.

Chiasmatype theory.

Two genes located close to each other are less likely to form chiasmata between them. Crossing-over results the actual physical exchange.

Alfred H. Sturtevant - Morgan's student, crossing-over frequencies could be used to map the sequence of genes and the distance between genes.

Alfred H. Sturtevant

**Compiled data on recombination
Listed frequency of crossing-over
between pairs.**

yellow, white	0.5%
white, miniature	34.5%
yellow, miniature	35.4%

yellow, white 0.5%

white, minature 34.5%

yellow, minature 35.4%

- 1. yellow and white must be close**
 - recombination frequency is low.**
- 2. yellow and white must be far from minature**
 - high recombination frequency for both.**
- 3. Minature shows more recombination with yellow than white.**
 - White must be between yellow and minature.**

**one map unit = 1% recombination
between genes.**

linkage also occurs on autosomes

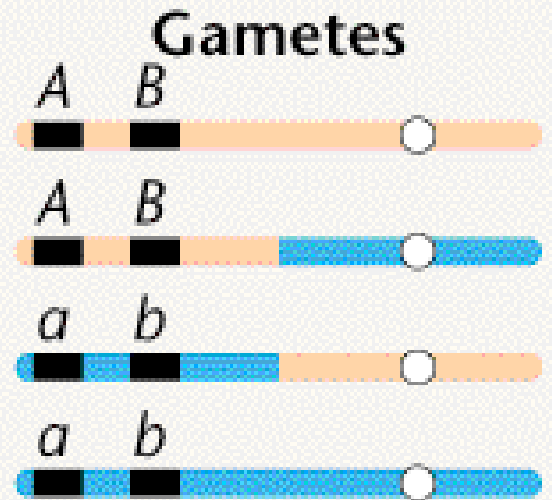

**In *Drosophila* crossing-over occurs only
in females.**

Why should relative distance between loci affect recombination?

A limited number of random cross overs occur during meiosis.

The closer the two loci, the less likely that crossing-over will occur.

(a) Exchange

Exchange occurs but does not intervene between the genes

(b) Exchange

Exchange occurs and does intervene between the genes

Crossing-over occurs in four strand tetrad stage.

Single cross over between two nonsister chromatids, other two chromatids will be unchanged.

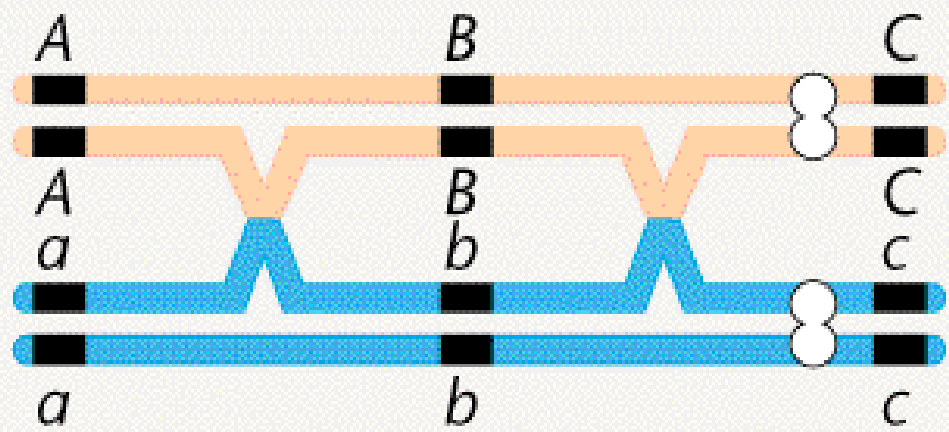

If single cross over occurs 100% of time, 50% of gametes formed affected.

For single cross over, maximum percentage of recombinant gametes is 50%.

Multiple crossovers

- multiple exchanges between nonsister chromatids.**

Probability of double cross over between 2 loci is product of individual probabilities.

Double-crossover gametes

Noncrossover gametes

A and B = 20% recombinant

B and C = 30% recombinant

**Probability of double crossover between
A and C is:**

$$.2 \times .3 = .06 \text{ or } 6\%$$

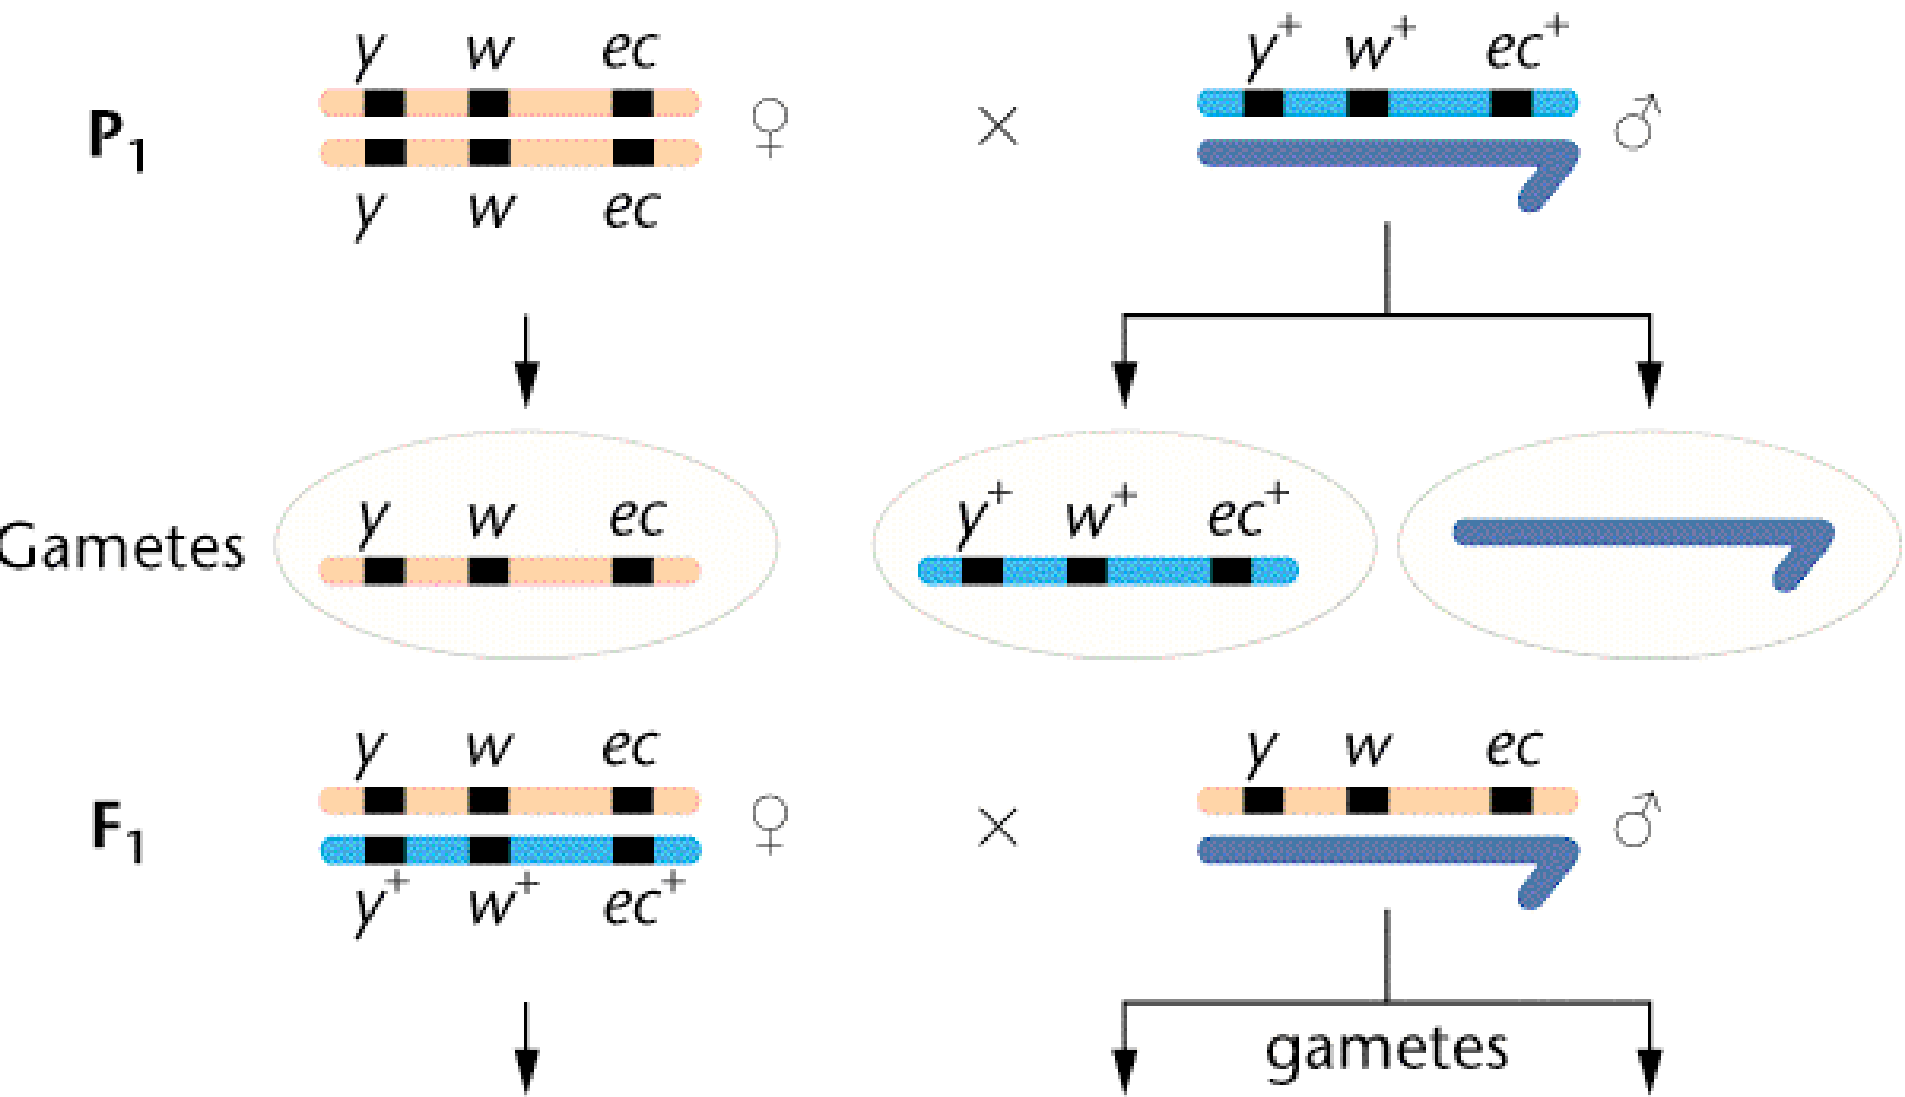

Three-Point Mapping

Have 3 genes and want to determine which gene is in the middle.

Three-Point Mapping

Three criteria must be met:

- 1. Genotype of organism producing the crossover gametes must be heterozygous at the loci.**
- 2. Each phenotypic class must reflect the genotype of the gametes of the parents producing it.**
- 3. A sufficient number of offspring must be produced.**

Noncrossover F_2 phenotypes
- highest proportion.

double crossover
- least

Remaining are from single crossovers.

Origin of female gametes	gametes			F ₂ phenotype	Observed number
NCO 	1			y w ec	4685
	2			y ⁺ w ⁺ ec ⁺	4759
SCO 	3			y w ⁺ ec ⁺	80

Determining the Gene Sequence

- 1. Assign order of genes along each homologue of the heterozygous parent.**
- 2. Following a double crossover, the middle allele will end up in the middle of the other two alleles on the other homologue**

Three theoretical sequences

Map distances - any two genes must consider all exchanges.

$$\mathbf{y \text{ and } w = 1.5\% + .06\% = 1.56\%}$$

$$\mathbf{w \text{ and } ec = 4.0\% + .06\% = 4.06\%}$$

In maize, the recessive mutant genes *bm* (brown midrib), *v* (virescent seedling) and *pr* (purple aleurone) are linked on chromosome 5. Assume that a female plant is known to be heterozygous for all three traits. Nothing is known about the arrangement of the mutant alleles on the paternal and maternal homologs of this heterozygote, the sequence of the genes, or the map distances between the genes. What genotype must the male have to allow successful mapping?

- 1. What is the correct heterozygous arrangement of the alleles in the female parent?**

(a) Possible allele arrangements and gene sequences in a heterozygous female

(b) Actual results of mapping cross

Phenotypes of offspring	Number	Total and percentage	Exchange classification
+ v <i>bm</i>	230	467	Noncrossover
<i>pr</i> + +	237	42.1%	(NCO)
+ + <i>bm</i>	82	161	Single crossover
<i>pr</i> v +	79	14.5%	(SCO)
+ v +	200	395	Single crossover
<i>pr</i> + <i>bm</i>	195	35.6%	(SCO)
<i>pr</i> v <i>bm</i>	44	86	Double crossover
+ + +	42	7.8%	(DCO)

	Allele arrangement and sequence	Test cross phenotypes	Explanation
(a)		+ v bm and pr + +	Noncrossover phenotypes provide the basis of determining the correct arrangement of alleles on homologs
(b)		+ + bm and pr v +	Expected double crossover phenotypes if v is in the middle
(c)		+ + v and pr bm +	Expected double crossover phenotypes if bm is in the middle
(d)		v pr bm and + + +	Expected double crossover phenotypes if pr is in the middle (<u>actually realized</u>)
(e)		v pr + and + + bm	Given that (a) and (d) are correct, single crossover product phenotypes when exchange occurs between v and pr
(f)		v + + and + pr bm	Given that (a) and (d) are correct, single crossover product phenotypes when exchange occurs between pr and bm
(g)	Final map		

2. What is the correct sequence of the genes?

$$\begin{array}{ccc} \underline{+ \quad v \quad bm} & \underline{+ \quad bm \quad v} & \underline{v \quad + \quad bm} \\ pr \quad + \quad + & pr \quad + \quad + & + \quad pr \quad + \end{array}$$

Only last choice will yield v pr bm and +++ following double cross-overs.

3. What is the distance between each pair of genes?

+	+	bm	14.5%
			+7.8
v	pr	+	-----
			22.3

v	+	+	35.6%
			+7.8
+	pr	bm	-----
			43.4

Linkage or genetic map

- use frequency of recombination to measure distant between genes.**

Syntenic

- genes on the same chromosome**
